# Looping

# Repeat statement

Sometimes you need to repeat a statement a number of times. That's where the *loop* comes in. A loop has a counter, called a *loop variable*, which (usually) ranges from a lower bound to an upper bound.

Here is the syntax in the simplest case:

```
for (int var=low; var<upper; var++) {  
    statements;  
}
```

*C difference:* Use `-std=c99`.

# Exercise 1

Read an integer value, and print 'Hello world' that many times.

# Loop syntax

- The loop variable can be defined outside the loop:

```
int var;  
for (var=low; var<upper; var++) {
```

- The stopping test be any test; can even be empty.
- The increment can be a decrement or something like `var*=10`
- Any and all of initialization, test, increment can be empty:  
`for(;;) ...`

# Nested loops

Traversing a matrix:

```
for (int i=0; i<m; i++)  
    for (int j=0; j<n; j++)  
        ...
```

# Indefinite looping

Sometimes you want to iterate some statements not a predetermined number of times, but until a certain condition is met. There are two ways to do this.

First of all, you can use a 'for' loop and leave the upperbound unspecified:

```
for (int var=low; ; var=var+1) { ... }
```

# Break out of a loop

This loop would run forever, so you need a different way to end it.  
For this, use the *break* statement:

```
for (int var=low; ; var=var+1) {  
    statement;  
    if (some_test) break;  
    statement;  
}
```

# Skip iteration

```
for (int var=low; var<N; var++) {  
    statement;  
    if (some_test) {  
        statement;  
        statement;  
    }  
}
```

Alternative:

```
for (int var=low; var<N; var++) {  
    statement;  
    if (!some_test) continue;  
    statement;  
    statement;  
}
```

# While loop

The other possibility is a *while* loop, which repeats until a condition is met. Syntax:

```
while ( condition ) {  
    statements;  
}
```

or

```
do {  
    statements;  
} while ( condition );
```

The while loop does not have a counter or an update statement; if you need those, you have to create them yourself.

# While syntax 1

```
cout << "Enter a positive number: " ;  
cin >> invar;  
while (invar>0) {  
    cout << "Enter a positive number: " ;  
    cin >> invar;  
}  
cout << "Sorry, " << invar << " is negative" << endl;
```

Problem: code duplication.

## While syntax 2

```
do {  
    cout << "Enter a positive number: " ;  
    cin >> invar;  
} while (invar>0);  
cout << "Sorry, " << invar << " is negative" << endl;
```

More elegant.

## Exercise 2

Find all triples of integers  $u, v, w$  under 100 such that  $u^2 + v^2 = w^2$ . Make sure you get unique triples and leave out permutations of something you already found.

## Exercise 3

One bank account has 100 dollars and earns a 5 percent per year interest rate. Another account has 200 dollars but earns only 2 percent per year. After how many years will the amount of money in both accounts be the same?

## Exercise 4

The integer sequence

$$u_{n+1} = \begin{cases} u_n/2 & \text{if } u_n \text{ is even} \\ 3u_n + 1 & \text{if } u_n \text{ is odd} \end{cases}$$

leads to the Collatz conjecture: no matter the starting guess  $u_1$ , the sequence  $n \mapsto u_n$  will always terminate.

For  $u_1 < 1000$  find the values that lead to the longest sequence: every time you find a sequence that is longer than the previous maximum, print out the starting number.

## Project Exercise 5

Read an integer, and test for all smaller numbers whether they are a divisor of that number. If there is a divisor, print out that number.

Print a final message

Your number is prime

or

Your number is not prime
